## 1 Introduction

Recent advances in cryo-electron tomography (cryoET) allow to obtain high resolution representations of macromolecular complexes as their native cellular environment. This makes cryoET much more accessible with other methods. Turk and Buzzeo [2020]. In cryoET, the imaged sample is in most cases a 100–300 nm thick slice of a frozen cell. From this slice, projections are taken at a range of angles using a transmission electron microscope (TEM) from different rotation (tilt) angles. An artifact free reconstruction would require measurements using tilt angles that would complete the full circle. However, due to the physical limitations of the specimen holder, only a range of 140° can be recorded. The missing tilt images later on result in a so-called missing-wedge in the 3D reconstruction (reconstruction artifacts). In addition, the beam already damages the sample during imaging, so only a low dose electron can be used to image a biological specimen. The low dose in combination with the presence of tilt angles results in the acquisition of images being very noisy. Consequently, the identification of molecules within these reconstructions is a daunting task. Particle identification is however necessary as the particles need to be tracked over time to identify the underlying biological structures. While cryoET has led to a large number of breakthroughs, providing hitherto unknown detail in the molecular architecture of cells Zemaitis et al. [2021], O’Shea et al. [2020], Marqusee et al. [2016], the above mentioned challenges still hinder the widespread use of cryoET in the larger cell biology and structural biology community. In this context, the development of new reliable tools for the reconstruction of cryoET data which is however obstructed by the lack of efficient accessible and annotated data to develop the software tools on.

## 1.1 SHREC simulator

To overcome the problem with the lack of data, in 2019, the organizers of SHREC<sup>1</sup> – 3D Shape Retrieval Contest included a new track titled *Classification in Cryo-Electron Tomography*. The organizers of this track proposed a task of localization and classification of biological particles in cryo-electron tomograms. Every year since, experts from

# Motivation

---

- particle localization and classification are important challenges
- supervised deep learning methods have been successfully introduced
- large amounts of training data is required (usually manually labeled)
- some small and/or scarce particles are impossible to manually label

# Main Contributions

We propose FakET:

- an efficient method for **simulating projections** from a TEM
- based on **neural style transfer**
- generates data of comparable quality to state-of-the-art methods
- **much faster, requires less memory, and scales well** to standard tomogram sizes
- valuable tool for researchers in structural biology

**Abstract**

Rendering the semantic content of an image in different styles is a difficult image processing task. Arguably, a major limiting factor for previous approaches has been the lack of image representations that can separate image representation from style. Here we use image representations derived from Convolutional Neural Networks optimized for object recognition, which have been shown to capture both content and style. We introduce a Neural Algorithm of Artistic Style that can separate and recombine the image content and style of visual images. The algorithm allows us to produce new images of high perceptual quality that are visually similar to their ancestors photograph with the appearance of numerous well-known artworks. Our results provide new insights into the deep image representations learned by Convolutional Neural Networks and demonstrate their potential for high-level image synthesis and manipulation.

ABSTRACT

Cryo-electron tomography (cryo-ET) is an imaging technique that allows us to three-dimensionally visualize both the structural details of macromolecular assemblies under near-native conditions and its cellular context. This article compares methods with learned samples during electron dose. The latter yields the dose tolerance rate, which is a measure of the amount of dose that can be applied before damage. Dose tolerance can be obtained by averaging volumes, each depicting copies of the molecule, allowing more dose to be applied. The dose tolerance rate is proportional to the dose tolerance of the molecule, but challenging due to the low signal-to-noise ratio. Computational innovation is key to mine biological information from cryo-electron tomography.

To validate our approach we used a novel simulated dataset to benchmark different methods of localisation and classification of biological macromolecules in cryo-electron tomograms. Our publicly available dataset contains 10 cryo-ET volumes of 10 different macromolecular complexes. Each volume contains roughly different types of organelles, varying in size, function and structure. We used two different types of learning-based methods to identify particles in the volumes. One set of results presents particle results obtained with learning-based methods and trained on the simulated dataset, as well as a baseline template matching, a traditional method widely used in cryo-ET research. We also present results obtained with DeepFinder, a learning-based method that performs well in tasks for which performance degrades rapidly as the size decreases. We found that neural networks can achieve significantly better localisation and classification performance, in particular considering networks with focus on high-resolution details such as those found in the DeepFinder network.

## SHREC 2020: Classification in cryo-electron tomograms, Gubins, Ilja, et al. Computers & Graphics (2020).

- SHREC Challenge (active in 2019, 2020, 2021)
- particle localization and classification tasks
- simulates a set of 10 cryo-electron tomograms
- DeepFinder was one of the most successful methods

# Deep Finder

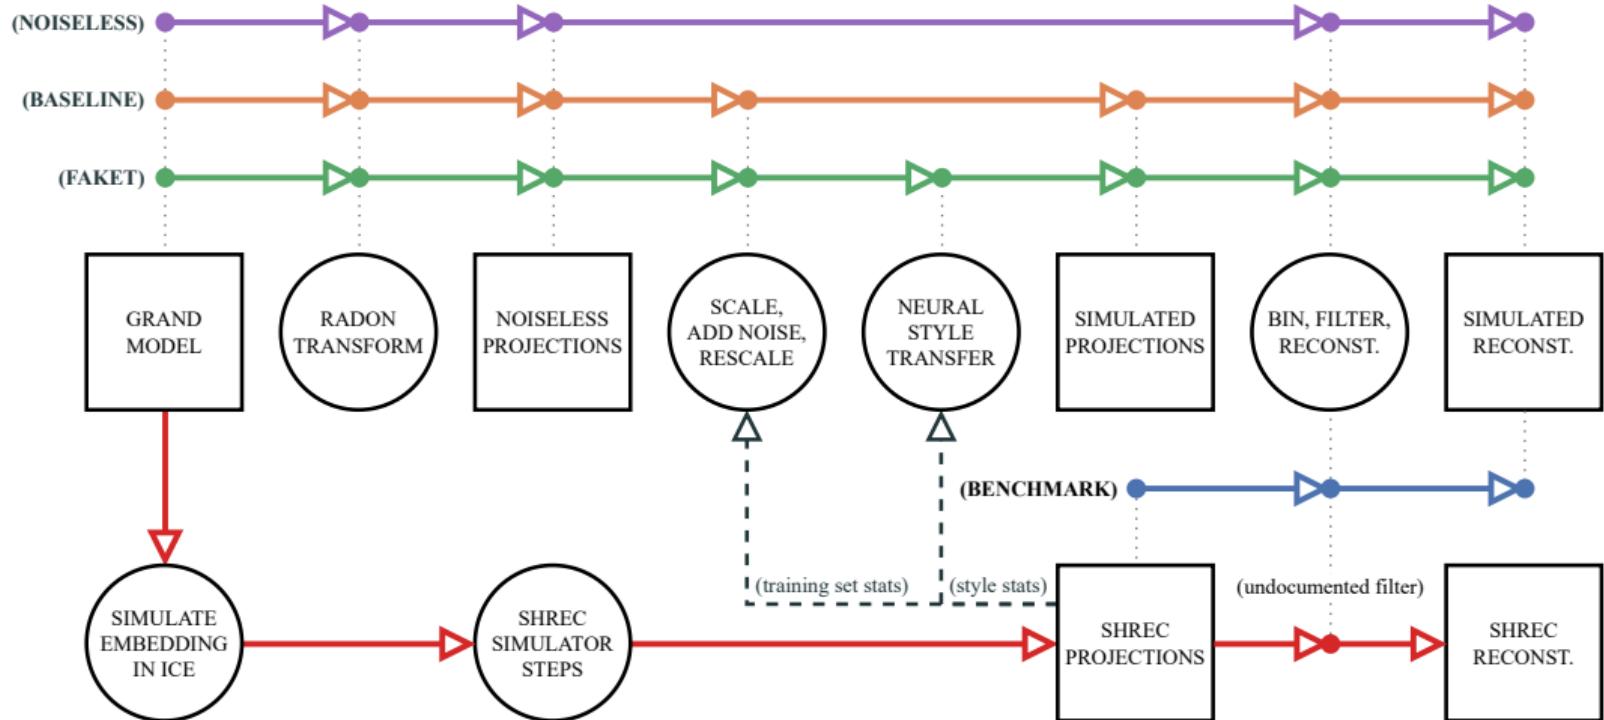

The image shows the front cover of a journal issue of *Nature Methods*. The title of the article is "Deep learning improves macromolecule identification in 3D cellular cryo-electron tomograms". The authors listed are Emmanuel Moebel, Antonio Martinez-Sánchez, Lorenz Lamm, Ricardo D. Righetto, Wojciech Wietryska, Sahradha Albert, Damien Larivière, Eric Fouquetin, Stefan Pfeffer, Julio Ortiz, Wolfgang Baumeister, Tingting Peng, Benjamin D. Engel, and Charles Kervran. The journal's logo and the word "ARTICLES" are visible at the top. Below the title, there is a short abstract and a large image showing a 3D reconstruction of cellular structures.

Deep learning improves macromolecule identification in 3D cellular cryo-electron tomograms, Moebel, Emmanuel, et al. *Nature methods* (2021).

- Proposes DeepFinder neural network
- for particle localization and classification
- evaluates on SHREC Challenge data set
- evaluates also on experimental data set

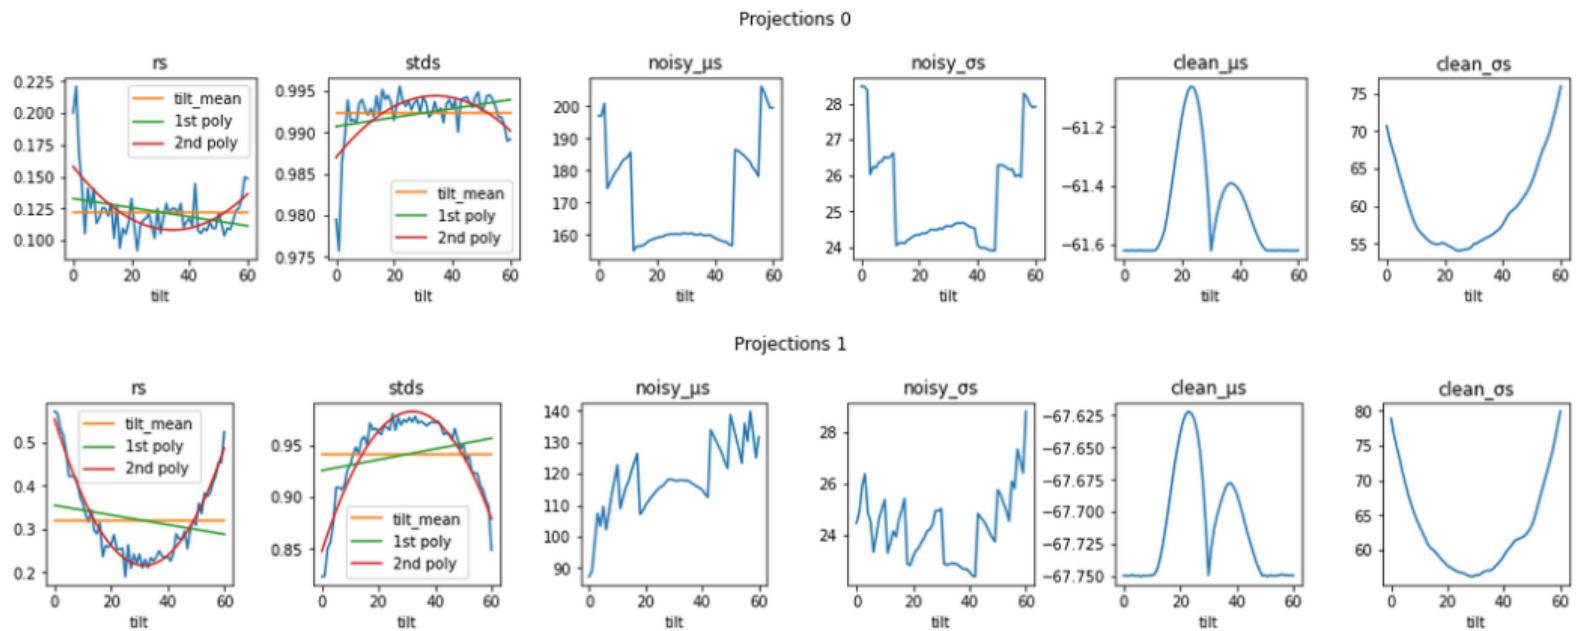

## Methods

# Conclusions

---

- FAKET, a novel method for simulating the forward operator of TEM
- FAKET combines additive noise and neural style transfer (NST)
- allows practitioners to generate synthetic cryo-electron tilt series
- $750\times$  faster and uses  $33\times$  less memory than SHREC simulator
- GPU accelerated but can be also computed only using CPUs
- provides practitioners with annotated data to train neural networks
- provides annotated data for particles that are hard to manually label
- useful among other things in particle localization and classification
- capable of simulating large tilt series common in experimental environments
- open-source

## Outlook

---

- validation on real experimental data
- fine-tuning the NST network on tomographic data
- making user-friendly CLI interface

# The Goal

Happy structural biologists who use FakET to solve their problems. Laboratory, emotional, excited, happy, hyper-realistic, portrait, male and female, there is an electron microscope in the background, they are looking at a computer display showing a detail of a cell.

Image generated using:  
<https://midjourney.com>
